I – INTRODUÇÃO

Este estudo consiste na coleta, processamento e análise de consistência das informações hidrológicas referentes aos reservatórios integrantes do sistema de controle de cheias da bacia hidrográfica do rio *Capibaribe* no estado de Pernambuco, com destaque para as caracterizações e atributos de múltiplos usos pertinentes aos reservatórios *Jucazinho* e *Carpina*.

As etapas do trabalho foram essencialmente as seguintes:

1. Coleta dos dados;
2. Processamento das informações;
3. Análise dos dados processados;
4. Emissão de relatório.

Um projeto de planejamento de recursos hídricos visando a otimização de um sistema de reservatórios integrados necessita, como base, de dados hidrológicos consistentes a respeito do sistema. Este trabalho tem a finalidade de fornecer dados hidrológicos consistentes para um projeto de mestrado que visa determinar formas de operação ótima para o sistema integrado dos reservatórios *Jucazinho* e *Carpina*, objetivando um melhor aproveitamento dos recursos hídricos da região.

II – O SISTEMA JUCAZINHO-CARPINA

2.1 – LOCALIZAÇÃO

A região compreendida pelas barragens em série de Jucazinho e Carpina, construídas ao longo do rio Capibaribe, está situada na porção nordeste da zona geográfica do Agreste do Estado de Pernambuco, no Nordeste do Brasil, entre as latitudes $7^{\circ} 43'$ e $8^{\circ} 19'$ sul e longitude de $35^{\circ} 19'$ e $36^{\circ} 42'$ a oeste de Greenwich. Com uma superfície de 5947 km², é parte integrante da bacia hidrográfica do rio Capibaribe cobrindo as suas partes alta e média, o que representa cerca de 78,9 % de toda a área de drenagem daquele curso d'água (o mapa da região é mostrado no Anexo 1).

Limita-se ao norte com o Estado da Paraíba e a bacia hidrográfica do rio Goiana; ao sul com a bacia hidrográfica do rio Ipojuca; a leste com a parte baixa da bacia hidrográfica do rio Capibaribe; a oeste com o Estado da Paraíba e bacia hidrográfica do rio Ipojuca.

A região do sistema de reservatórios Jucazinho-Carpina , no que diz respeito aos dados cartográficos e topográficos, é abrangida pelas Cartas Plani-Altimétricas a seguir listadas, cujas restituições fotogramétricas foram executadas pela *Aerofoto Cruzeiro Sociedade Anônima*, na escala 1:100.000 e eqüidistância das curvas de nível de 50 metros, publicadas pelo Ministério do Exército/SUDENE.

Tabela 1.1 – Lista das cartas plani-altimétricas que abrangem a região do sistema Jucazinho-Carpina

Carta	Número	Ano
Limoeiro	SB25-Y-C-V	1974
Vitória de Sto. Antão	SC25-V-A-II	1986
Surubim	SB25-Y-C-IV	1986
Caruarú	SB25-Z-D-VI	1984
Sta. Cruz do Capibaribe	SB24-Z-D-VI	1984
Belo Jardim	SC24-X-B-III	1986
Sumé	SB24-Z-D-V	1970
Pesqueira	SB24-X-II	1986

2.2 – CLIMATOLOGIA

A bacia dos açudes Juazinho-Carpina, apresenta predomínio do clima semi-árido com pouco ou nenhum excesso hídrico, do tipo *Dd* segundo a classificação climática de *Thorntwaite* e definições contidas no trabalho *Contribuições ao Estudo do Clima de Pernambuco* (Reis, 1970).

De modo geral, pode-se dizer que há um período de cinco meses mais chuvosos na região, concentrados entre março e julho (março aparecendo como o mais chuvoso), embora que ainda prevaleçam condições de semi-árido. Neste período acontece cerca de 65% a 68% da precipitação anual, sendo setembro, outubro e novembro os meses mais secos.

A precipitação total anual média na região atinge valores em torno de 700 mm, com máximos de 800 mm a 1000 mm em algumas áreas isoladas, regionalmente conhecidas como *brejos* de altitude, como é o caso das localidades de Brejo da Madre de Deus e Taquaritinga do Norte.

Entre os postos selecionados para os estudos, referencia-se a seguir os registros de totais anuais médios nas estações consideradas como bem representativas para cada sub-região da bacia.

Tabela 1.2 – Totais anuais médios nos postos pluviométricos representativos

Porção da Bacia Juazinho- Carpina	Posto	Altitude (m)	Período	Total Anual Médio (mm)
Baixa	Glória do Goitá	200	1963-1985	1071,5
	Carpina	184	1934-1988	1007,8
	Salgadinho	270	1957-1983	920,7
	Bengalas	290	1963-1987	609,3
Média	Cumarú	395	1956-1991	820,5
	Surubim	380	1911-1985	644,8
	Toritama	376	1963-1989	550,5
	Carapotós	501	1962-1992	429,5
Alta	Taquaritinga do Norte	785	1963-1990	1132,1
	Jataúba	600	1962-1991	627,0

Sta. Cruz Capibaribe	472	1962-1987	503,3
Brejo Madre de Deus	646	1911-1987	850,2
Sítio Muquém	830	1967-1997	759,6
Lagoa do Félix	770	1967-1992	464,4

Pela situação geográfica da bacia, considerada sua pouca distância do mar (ponto mais a oeste dista cerca de 270 km), a região mais próxima do litoral sofre a influência dos sistemas meteorológicos de leste, de forma que o mês mais chuvoso se desloca para maio ou junho. A parte mais baixa da região, abaixo da cidade de Limoeiro até a barragem de Carpina, está sob influência direta das chuvas de inverno, se bem que possam existir influências secundárias convectivas, produzidas pelo centro orográfico situado a sudoeste, na Serra das Russas, com altitude de 800 m, distante cerca de 70 km do mar.

A região, como um todo, encontra-se envolvida pelas isoietas de 1000 mm e 500 mm, refletindo-se numa forte variabilidade espaço-temporal das chuvas.

A evaporação anual supera em muito o valor da precipitação, com lâminas atingindo cerca de 2200 mm. A maior evaporação média mensal é registrada no mês de janeiro atingindo valor de 231 mm. A temperatura média do ar nos meses mais secos, entre setembro e novembro, fica em torno dos 25 °C, tendo-se registrado máxima média de até 31,6 °C no mês de dezembro; os meses mais frios são junho a agosto; a temperatura média anual é de aproximadamente 24 °C, conforme registros da estação meteorológica de Surubim, operada pelo Instituto Nacional de Meteorologia – INMET.

A umidade relativa do ar, sendo um fator influenciado pela ocorrência de chuvas, apresenta-se com valores mais elevados no quadrimestre mais chuvoso, atingindo a média mensal de 78%. No mais seco apresenta um declínio, situando-se na faixa média mensal de 69% a 71%.

Os estudos dos ventos mostram que as maiores velocidades ocorrem nos meses de julho, e de dezembro a fevereiro (média de 8 km/h), sendo que a média anual se aproxima de 6,5 km/h.

Assim como as médias de temperaturas e ventos, as médias de insolação apresentam certa homogeneidade durante o ano. De março ate agosto, a insolação se mantém em torno 170 horas médias mensais, atingindo 251 horas em outubro. A insolação por ano tem valor médio de 2400 horas.

2.3 – HIDROLOGIA SUPERFICIAL

A região é drenada pelo rio Capibaribe que nasce no extremo sudoeste, nas vertentes da serra do Jacarará, numa altitude de cerca de 1135 m, no município de Jataúba/PE.

Desde a sua nascente o rio Capibaribe, apresentando uma declividade média de 0,44 % (4,48 m/km), percorre cerca de 135 km e é barrado no município de Surubim para formar o açude de Jucazinho; caminhando na direção oeste-leste mais 54 km o Capibaribe é novamente barrado, formando o açude de Carpina, no município de mesmo nome, limite do sistema hídrico superficial deste estudo.

O rio Capibaribe, dentro da bacia Jucazinho-Carpina, possui alguns afluentes importantes destacando-se pela margem direita os riachos: Aldeia Velha; Tabocas; Carrapatos; das Éguas, riacho Caçatubada e o rio Cotunguba.. Pela margem esquerda os mais expressivos tributários são os riachos: Jataúba; Topada; Caraibeiras; Pará; Tapera e Caiaí.

O regime fluviométrico do rio Capibaribe, na área em estudo, apresenta as características comuns do semi-árido nordestino. Os escoamentos são função direta das chuvas e das características físicas da bacia. Em toda a área de drenagem aqui considerada, o regime fluvial do rio é intermitente. Somente a partir da cidade de Limoeiro, a jusante da barragem de Jucazinho e pouco a montante da barragem de Carpina, torna-se perene. Com o advento da construção da barragem de Jucazinho, ainda em fase de enchimento do lago, o trecho do rio Capibaribe entre os dois açudes (Jucazinho e Carpina), será perenizado por uma descarga mínima de regularização prevista em $2,7 \text{ m}^3/\text{s}$.

Por se tratar de uma região em que as precipitações pluviais se apresentam com distribuição mensal e interanual irregular, o mesmo se observa com relação aos deflúvios. Assim, coerentemente com o regime pluviométrico, a distribuição do escoamento ao longo do ano é também muito irregular. Na parte alta da bacia as descargas mais elevadas se concentram no quadrimestre de fevereiro a maio, não escoando freqüentemente entre setembro e dezembro. Nas partes média e baixa da bacia, as vazões mais representativas ocorrem nos meses de março a julho, com baixos escoamentos entre os meses de outubro a janeiro.

2.4 – FINALIDADES E DADOS TÉCNICOS DAS BARRAGENS

O sistema composto pelos dois reservatórios em série Jucazinho e Carpina, com área de drenagem total de 5947 km^2 e capacidade de acumulação totalizando $597 \times 10^6 \text{ m}^3$, representa cerca de 93 % de todo o estoque d'água de superfície que pode ser armazenado na bacia.

2.4.1– BARRAGEM DE CARPINA

A barragem de Carpina tem função de regularizar a vazão do rio Capibaribe em $300 \text{ m}^3/\text{s}$, evitando grandes enchentes a jusante, prejudiciais à Região Metropolitana do Recife, conforme concepção original da obra.

Conquanto se reconheça até hoje a importância da função protetora da barragem de Carpina, projetada para acumulação nula, a exclusividade desse papel vem sendo questionada desde há algum tempo por interessados na questão, fazendo com que o reservatório hoje tenha compromissos de parcial utilização como fonte de recursos hídricos, seja para reforço do abastecimento do Recife, seja para sustentar irrigações não formais em terras invadidas no entorno de sua bacia hidráulica, quanto em alguma outras área adjacentes à barragem, cujas demandas não se conhece com precisão. No entanto, a Companhia Pernambucana de Saneamento – COMPESA, informalmente operando a barragem, vem mantendo desde meados de 1992 uma acumulação média de não mais do que $56.600.000 \text{ m}^3$, correspondente à cota 104 m do reservatório, permitindo-se derivar uma vazão de regularização para jusante na intenção de alimentar as captações a fio d'água de Tiúma e Castelo no mesmo rio Capibaribe, que derivam em média uma vazão de cerca de $1,3 \text{ m}^3/\text{s}$ (Vazão de Projeto das Captações = $1,5 \text{ m}^3/\text{s}$) que são injetados no sistema (adutora) de Tapacurá para reforço do abastecimento de Recife.

A seguir são indicados os dados técnicos da barragem de Carpina:

- **Rio barrado:** Capibaribe
- **Município:** Carpina
- **Área da bacia hidrográfica:** 5.999 km^2
- **Barragem constituída de um maciço de enrocamento com miolo de terra, com:**
 - Extensão total (900 m de maciço mais 730 m correspondentes a 4 diques): 1.720 m
 - Altura máxima: 42 m
 - Cota de coroamento: 124 m
 - Largura no coroamento: 8 m
 - Sangradouro de emergência tipo “Vallecito Dam”, cota 118 m

- Estrutura de tomada d'água em forma de caixa de 22,60 X 11 X 11,40 m (comprimento, largura e altura), dotada de 48 aberturas providas de grades de proteção, composta ainda de:

- Torre de comando com sistemas de acionamento das comportas, grades e stop-logs, incluindo ponte rolante.
- Galeria com dois condutos, cada uma com ϕ 4,50 m que cruza todo o corpo transversal da barragem, tendo na sua parte de montante, para cada conduto, uma comporta tipo vagão. Geração inferior das tubulações na cota 84,20 m.
- Bacia de dissipação de energia em concreto armado com largura de 15 m e 50 m de comprimento.
- **Área da bacia hidráulica na cota 118 m:** 24,65 km²
- **Volume de acumulação na cota 118 m:** 270.000.000 m³
- **Volume para atenuação de enchentes:** 189.000.000 m³
- **Volume morto (cota 89,0 m):** 1.190.000 m³
- **Volume útil:** 79.810.000 m³
- **Vazão efluente máxima (laminação da cheia):** 300 m³/s
- **Conclusão da obra:** 29 de maio de 1978
- **Administração do empreendimento:** DNOCS (COMPESA - Companhia Pernambucana de Saneamento)

2.4.2– BARRAGEM DE JUCAZINHO

A barragem de Jucazinho possui as seguintes finalidades:

- Abastecimento da cidade de Caruarú e mais 19 outras localidades do agreste pernambucano, beneficiando uma população estimada hoje em 384.000 habitantes (1997) e uma população de projeto (ano 2016) de 715.352 habitantes.
- Controle de enchentes do alto curso do rio Capibaribe, preservando as cidades a jusante, até Recife.
- Irrigação de cerca de 6.750 ha ao longo do rio.
- Piscicultura com produção estimada em cerca de 500 toneladas de pescado por ano.
- Perenização do leito do rio Capibaribe a jusante da barragem com uma descarga prevista de 2,72 m³/s.

Os dados técnicos da barragem são:

- **Rio barrado:** Capibaribe
- **Município:** Surubim
- **Área da bacia hidrográfica:** 4.772 km²
- **Barragem do tipo gravidade, com maciço em concreto compactado rolado (CCR), com:**
 - Extensão da crista: 442,0 m
 - Altura máxima: 63,2 m
 - Cota do coroamento: 299,0 m
 - Largura do coroamento: 8,0 m
 - Estrutura de tomada d'água tipo “Galeria com Torre”, com conduto de ϕ 2,0 m – acionamento de montante por comporta vazão e acionamento de jusante por dispersor Howell-Bunger.
 - Cota: 250,0 m
 - Descarga de regularidade (prevista: 2,72 m³/s)
 - Descarga máxima: 35,0 m³/s
 - Vertedouro principal tipo “Stepped Spilway”, em concreto, com:
 - Cota da soleira: 292,0 m
 - Comprimento: 170,0 m
 - Descarga máxima na cota 298,0 m: 5446,7 m³/s
 - Vertedouros auxiliares (02) tipo “Canal Lateral”, em concreto, com:
 - Cota da soleira: 295,0 m
 - Comprimento total
 - Pela margem esquerda: 57,0 m
 - Pela margem direita: 57,0 m
 - Descarga máxima total: 1.291,3 m³/s
- **Área da bacia hidráulica na cota 292,0 m:** 15,00 km²
- **Volume de acumulação na cota 292,0 m:** 327.035.812 m³
- **Volume para atenuação de enchentes:** 100.000.000 m³
- **Volume morte (cota 250,0 m):** 7.093.175 m³
- **Volume útil:** 219.942.637 m³
- **Vazão afluente máxima (descarga de restrição para jusante):** 1.000 m³/s
- **Conclusão da obra:** Fevereiro de 1998
- **Administração do empreendimento:** DNOCS

2.5 – MONITORAMENTO HIDROMETEOROLÓGICO

Fazendo parte da bacia do rio Capibaribe, como já descrito, a sub-bacia Jucazinho-Carpina aproveita boa parte da rede de monitoramento hidrometeorológico implantada naquela bacia, que pode ser descrita como a seguir.

2.5.1 – REDE PLUVIOMÉTRICA

Originária da rede básica da SUDENE e desde 1992 mantida e operada pelo Estado de Pernambuco, atualmente sob a responsabilidade da Secretaria de Recursos Hídricos, a rede pluviométrica da bacia Jucazinho-Carpina tem cerca de 35 postos em operação, com uns poucos, mais antigos, com registros desde 1911. Nas cercanias da bacia foram selecionados outros 39 postos, para complementação dos estudos hidrológicos.

Estão disponíveis dados diários e mensais nos Bancos de Dados da SUDENE e da Secretaria de Recursos Hídricos do Estado de Pernambuco, cobrindo até o ano de 1985. Para alguns postos, já se tem dados até o ano de 1993. Os dados mensais, registrados até o ano de 1985, preliminarmente consistidas pela SUDENE, constam do trabalho *Dados Pluviométricos Mensais do Nordeste – Estado de Pernambuco/SUDENE – 1990*.

2.5.2 – REDE FLUVIOMÉTRICA

Engloba hoje 14 estações fluviométricas operadas pela Companhia de Pesquisa de Recursos Minerais – CPRM, para o Departamento Nacional de Águas e Energia Elétrica – DNAEE, do Ministério de Minas e Energia. Em poucos postos dispõe-se de descargas médias diárias e mensais desde 1956 a 1966.

No caso das estações de Toritama e de Limoeiro, cujos dados servem para os propósitos deste estudo, dispõe-se de descargas médias diárias e mensais relativas aos períodos de abril/1966 a dezembro/1996, e outubro/1956 a dezembro /1996, respectivamente.

Recentemente, em setembro de 1997 a CPRM divulgou Relatório Técnico contendo resultado de análises e estudos de consistência de dados fluviométricos diários da bacia do rio Capibaribe (sub-bacia 39), envolvendo as 14 estações, cobrindo o período base 1984-1996.

As estações fluviométricas locadas na bacia Jucazinho-Carpina estão listadas na Tabela 1.3 , a seguir, anotando-se algumas observações de avaliações sobre a qualidade dos dados ali obtidos, feitas em setembro de 1997 pela CPRM.

Tabela 1.3 – Relação das estações fluviométricas

Código	Rio	Estação	Área Drenagem (km ²)	Tipo da Estação	Período Base	Avaliação Final
39098000	Tapera	Tapera	254	FD	1986-1996	Medições insuficientes/Desativar
39100000	Capibaribe	Sta. Cruz Capibaribe	1.557	FD	1986-1996	Cotas de boa qualidade/imprecisões na curva-chave
93130000	Capibaribe	Toritama	2.407	FRDSQ	1985-1996	Observações de boa qualidade/descargas geradas com boa confiabilidade
39140000	Capibaribe	Salgadinho	5.108	FD	1984-1996	Descargas geradas de boa qualidade
39145000	Capibaribe	Limoeiro	5.360	FRDSQ	1983-1996	Descargas geradas devem ser usadas com restrições/Curvas-Chave com imprecisões

F=Fluviometria; FR=Fluviográfica; D=Medição de Descarga Líquida; Q=Qualidade da Água;

S=Sedimentométrica

A figura do Anexo 2 , apresenta o diagrama unifilar da rede fluviométrica da bacia do Capibaribe, posicionando as principais barragens do sistema hídrico.

2.5.3 – REDE DE ESTAÇÕES CLIMATOLÓGICAS

Na bacia do rio Capibaribe estão locadas atualmente somente duas estações meteorológicas – Surubim e Recife, operadas pelo Instituto Nacional de Meteorologia- INMET, do Ministério da Agricultura, com dados históricos já publicados pela SUDENE (Normais Climatológicos da SUDENE)

No período 1961-1983, funcionou a estação experimental do então Instituto do Açúcar e do Álcool-IAA/PLANALSUCAR, em Carpina, cuja média de evaporação,

publicada no documento *Caracterização Edafoclimática das Regiões Canavieiras do Brasil – Pernambuco* de Koffler, N. F. (1986), atinge 1899mm/ano, enquanto em Surubim é registrada uma média de 2154mm/ano.

Para fins deste estudo, no que tange à caracterização climatológica da bacia, estão considerados os dados da estação de Surubim, operada desde 1930 pelo INMET. Para as avaliações das perdas por evaporação nas bacias hidráulicas das barragens de Jucazinho e de Carpina, estão considerados, respectivamente, os dados de evaporação do Tanque Classe A das estações de Surubim e de Carpina.

2.5.4 – REDE DE MONITORAMENTO DA QUALIDADE DA ÁGUA

a) Rede operada pela CPRH

A rede de monitoramento de qualidade das águas superficiais, de responsabilidade da CPRH não contempla a maioria dos corpos d'água da bacia Jucazinho-Carpina.

Para avaliação da qualidade das águas, a CPRH utiliza indicadores que, de certo modo, se relacionam aos aspectos estético, sanitário e econômico, dando-se muito ênfase ao Índice de Qualidade de Água – IQA, que engloba em um só número uma série de parâmetros. O monitoramento feito pela CPRH objetiva, principalmente, o contínuo acompanhamento das condições dos cursos d'água, sendo sistemático para os rios litorâneos, para observar se os mesmos permanecem nas classes nas quais foram enquadrados.

b) Rede operada pela COMPESA

Conforme o PQA-PE, a COMPESA, como órgão mantenedor dos sistemas de abastecimento de água existentes na bacia em referência, não dispõe de rede adequada de monitoramento de qualidade dos cursos d'água da bacia.

As informações são obtidas de um “monitoramento menos intensivo”, basicamente concentrados nos mananciais abastecedores dos sistemas de tratamento de água, que tem servido para avaliações iniciais ou mesmo conclusivas sobre as características fisico-químicas e bacteriológicas da água bruta. Mesmo as análises sendo de boa qualidade, o monitoramento é pouco satisfatório, mas garante que a água bruta, após tratamento seja fornecida à população em conformidade com os padrões de potabilidade.

2.6 – HIDROLOGIA SUBTERRÂNEA

A bacia em estudo está inserida, completamente, em área de embasamento cristalino, com reduzida capacidade de acumulação de águas subterrâneas que, regra geral, apresentam elevadores teores de sais, tornando as muitas vezes inadequadas para consumo humano.

De acordo com dados contidos no Plano Estadual de Recursos Hídricos de Pernambuco-PERH/PE (1998), os parâmetros estatísticos dos dados de 460 poços perfurados no domínio das rochas cristalinas podem ser vistos conforme a Tabela 1.4.

Tabela 1.4 – Parâmetros estatísticos dos poços

Parâmetro Estatístico	Profundidade (m)	Nível Estático (m)	Nível Dinâmico (m)	Vazão (m ³ /h)
Média	49,70	7,00	24,70	3,20
Desvio Padrão	16,80	6,70	14,90	3,90
Coef. Variação	33,80	95,71	60,32	121,87
Valor Máximo	130,00	40,00	89,00	40,00
Valor Mínimo	11,00	0,00	0,10	0,00

III – DADOS COLETADOS

3.1 – GENERALIDADES

Foram analisados os dados pluviométricos de postos considerados como representativos (postos de referência) para a região do sistema Jucazinho-Carpina. A relação dos postos pluviométricos é mostrada na Tabela 3.1 abaixo.

Tabela 3.1 – Relação dos postos pluviométricos estudados nas duas bacias

Postos para Jucazinho	Algodão do Manso; Belo Jardim; Brejo da Madre de Deus; Carapotós; Cumaru; Jataúba; Mandaçaia; Poção; São Caetano; St. Barriguda; Sta. Cruz do Capibaribe; Sta. Maria da Paraíba; Surubim; Taquaritinga do Norte; Toritama; Vertentes; Vila do Pará
Postos para Carpina	Apoti; Bengalas; Bezerros; Bom Jardim; Buenos Aires; Cumaru; Gravatá; Limoeiro; Mata Virgem; Russinha; Salgadinho; St. Barriguda; Surubim; Umbuzeiro

Foram desenvolvidos programas de computador para preenchimento de falhas, homogeneização e cálculo da pluviometria média.

Os programas foram escritos usando-se a linguagem do software matemático MATLAB (*High-Performance Numeric Computation and Visualization Software*). MATLAB é uma abreviação para *Matrix Laboratory*. É um ambiente computacional técnico de alto desempenho em cálculo e visualização numérica. O MATLAB integra análise numérica, cálculo matricial, processamento de sinais, e gráficos em um ambiente de uso simples onde problemas e soluções são expressos da mesma forma como são escritos matematicamente: sem o uso da tradicional programação em determinadas linguagens.

O MATLAB é um sistema iterativo no qual o dado elementar básico é uma matriz que não requer dimensionamento. Isso nos permite resolver muitos problemas numéricos em um período de tempo menor do que eles levariam para ser escritos em uma linguagem tal como *Fortran*, *Basic* ou *C*.

IV – ANÁLISE DOS DADOS

4.1 – GENERALIDADES

No estudos dos dados de chuva foram desenvolvidos programas de preenchimento de falhas, homogeneização e determinação da precipitação média.

4.2 – PREENCHIMENTO DE FALHAS

Muitas estações pluviométricas apresentam falhas em seus registros devido à ausência do observador ou por defeitos no aparelho. Entretanto, como há necessidade de se trabalhar com séries contínuas, essas falhas devem ser preenchidas.

A princípio foi feito um programa denominado *pluv* para o preenchimento de falhas dos postos de referência de Jucazinho e Carpina. O programa foi desenvolvido com o seguinte princípio: designando por X a estação que apresenta falhas e por A , B e C as estações vizinhas, pode-se determinar a precipitação P_X do posto X pela expressão:

$$P_X = P_A \cdot \text{Corr}_A^X + P_B \cdot \text{Corr}_B^X + P_C \cdot \text{Corr}_C^X \quad (4.1)$$

onde P_A , P_B e P_C são as precipitações medidas nos postos A , B e C , respectivamente, e Corr_A^X , Corr_B^X e Corr_C^X são as correlações entre o posto com falhas X e os demais postos A , B e C .

Abaixo é mostrado um trecho do programa *pluv*.

Quadro 4.1 – Trecho exemplo do programa para preenchimento de falhas

```

A = corrcoef(X,Y);
Corr_pfalha_p2(j) = abs(A(1,2));

4.3 – HOMOGENEIZAÇÃO

A *Análise de Duplas Massas* foi o método utilizado para se verificar a homogeneidade dos dados de precipitação, isto é, se houve alguma anormalidade na estação pluviométrica, tais como mudança de local ou das condições do aparelho ou modificação no método de observação.

Este método consiste em se construir uma curva dupla acumulativa, na qual são selecionados os totais anuais acumulados de um determinado posto e a média acumulada

dos totais anuais de todos os postos da região, considerada homogênea, sob o ponto de vista meteorológico.

Embora possa acontecer que o número de anos em que o posto foi operado nas condições iniciais seja maior do que nas atuais, é mais interessante corrigir os dados referindo-se às últimas. Isso porque, a qualquer instante, pode-se fazer uma inspeção local e conhecer o estado de operação e conservação do mesmo na atualidade.

Dessa forma, construiu-se um programa de nome *homog*, com base na *Análise de Duplas Massas*, para a homogeneização dos dados pluviométricos preenchidos anteriormente. A seguir é mostrada a relação dos postos cujos dados foram homogeneizados e seus respectivos postos vizinhos.

Tabela 4.1 – Postos homogeneizados para Jucazinho

Nome do Posto	Postos Vizinhos
Algodão do Manso	Sta. Cruz do Capibaribe; Mata Virgem; Vertentes; Surubim; Toritama; Mandaçaia
Belo Jardim	Poção; São Caetano; Brejo da Madre de Deus; Jataúba; Mandaçaia; Sta. Maria da Paraíba
Brejo da Madre de Deus	Sta. Cruz do Capibaribe; Mandaçaia; Jataúba; Poção; Belo Jardim; Vila do Pará
Carapotós	Bezerros; São Caetano; Toritama; Belo Jardim; Caruarú; St. Barriguda
Cumarú	Bom Jardim; Surubim; Algodão do Manso; Umbuzeiro; Mata Virgem; St. Barriguda
Jataúba	Sta. Cruz do Capibaribe; Toritama; Mandaçaia; Poção; Sta. Maria da Paraíba; Vila do Pará; Brejo da Madre de Deus
Mandaçaia	Sta. Cruz do Capibaribe; Carapotós; Toritama; Jataúba; Brejo; Belo Jardim
Poção	St. Muquém; Mandaçaia; Sta. Maria da Paraíba; Belo Jardim; Jataúba; Brejo

	da Madre de Deus
São Caetano	Bezerros; Carapotós; Cachoerinha; Caruarú; St. Barriguda
St. Barriguda	Sta. Cruz do Capibaribe; Algodão do Manso; Gravata; Bezerros; Carapotós; São Caetano; Vertentes; Surubim; Toritama; Mandaçaia
Taquaritinga do Norte	Sta. Cruz do Capibaribe; Mata Virgem; Vertentes
Sta. Cruz do Capibaribe	Vila do Pará; Jataúba; Vertentes; Toritama; Mandaçaia; Riacho de Sto. Antônio
Sta. Maria da Paraíba	Poção; St. Muquém; Jataúba; Belo Jardim; Congo; Mandaçaia
Surubim	Mata Virgem; Vertentes; Umbuzeiro; Cumarú; Algodão do Manso
Toritama	Sta. Cruz do Capibaribe; Carapotós; Algodão do Manso; Vertentes; Mandaçaia; St. Barriguda
Vertentes	Algodão do Manso; Toritama; Surubim; Sta. Cruz do Capibaribe; Mata Virgem; Vila do Pará
Vila do Pará	Jataúba; Sta. Cruz do Capibaribe; Barra de São Miguel; Poço Fundo; Congo

Tabela 4.2 – Postos homogeneizados para Carpina

Nome do Posto	Postos Vizinhos
St. Barriguda	Sta. Cruz do Capibaribe; Algodão do Manso; Gravata; Bezerros; Carapotós; São Caetano; Vertentes; Surubim; Toritama; Mandaçaia
Bezerros	Caruarú; St. Barriguda; Gravatá; São Caetano

O gráfico a seguir é também construído pelo programa *homog* para cada posto trabalhado fornecendo ao usuário uma visualização melhor do processo de homogeneização. Neste exemplo vemos a homogeneização do posto Algodão do Manso, para Jucazinho. Todos os resultados de precipitações preenchidas e homogeneizadas se encontram nos Anexos III e IV para Jucazinho e Carpina, respectivamente.

Gráfico 4.1 – Exemplo de gráfico construído pelo programa de homogeneização

4.3 – PLUVIOMETRIA MÉDIA

A pluviometria média foi determinada através do *Método de Thiessen*, cujo princípio consiste em atribuir um fator de peso aos totais precipitados em cada aparelho, proporcionais à área de influência de cada um.

Essas áreas de influência (pesos) são determinadas em mapas da bacia contendo as estações, unindo-se os postos adjacentes por linhas retas e, em seguida, traçando-se as mediatriizes dessas retas formando polígonos. Os lados dos polígonos são os limites das áreas de influência de cada estação.

A precipitação média é calculada pela média ponderada, entre a precipitação P_i de cada estação e o peso a ela atribuído A_i que é a área de influência de P_i .

$$\bar{h} = \frac{\sum P_i \cdot A_i}{\sum A_i} \quad (4.2)$$

sendo \bar{h} a precipitação média e $\sum A_i$ a área total da bacia.

Portanto, com base no *Método de Thiessen*, foi desenvolvido um programa denominado *plumed* para o cálculo da pluviometria média nas bacias de Jucazinho e Carpina. A seguir é mostrada a relação dos postos com as respectivas áreas de influência calculadas através de mapas com os traçados dos polígonos de Thiessen.

Tabela 4.3 – Áreas de influência de Thiessen para os postos de Jucazinho

Nome do Posto	Área de Influência (km ²)
Algodão do Manso	264,2
Belo Jardim	46,1
Brejo da Madre de Deus	475,2
Carapotós	295,4
Cumarú	42,7
Jataúba	410,9
Mandaçaia	398,7
Poção	145,5
São Caetano	46,6
St. Barriguda	297,7
Taquaritinga do Norte	315,5
Sta. Cruz do Capibaribe	385,5
Sta. Maria da Paraíba	105,9
Surubim	60,4
Toritama	278,2
Vertentes	262,2
Vila do Pará	341,3
Área Total	4172

Tabela 4.4 – Áreas de influência de Thiessen para os postos de Carpina

Nome do Posto	Área de Influência (km ²)
St. Barriguda	42,6

Bezerros	54,7
Russinha	44,6
Bengalas	265,7
Apoti	7,7
Buenos Aires	18,6
Limoeiro	204,8
Bom Jardim	48,3
Umbuzeiro	68,9
Mata Virgem	161,3
Surubim	218,1
Salgadinho	251,4
Cumarú	286,9
Gravatá	101,4
Área Total	1775

Abaixo é mostrado um trecho do programa *plumed*. Os resultados de precipitações média para Juçazinho e Carpina se encontram nos Anexos V e VI, respectivamente.

V – CONCLUSÕES

A água é um bem essencial à vida e ao desenvolvimento econômico-social das nações. Trata-se de um recurso natural renovável que pode tornar-se escasso com o crescimento das populações, das indústrias e da agricultura.

Pela sua importância estratégica, este setor ressente-se ainda da necessidade de desenvolvimento e aprimoramento de métodos e técnicas próprias que possibilitem a sua utilização racional na promoção do crescimento econômico e do bem estar social do país.

Técnicas de otimização podem ser usadas como ferramentas que possibilitem uma melhor distribuição da água entre seus vários usuários, os quais representam diferentes, e muitas vezes conflitantes usos da mesma. Os resultados obtidos neste trabalho fornecerão suporte ao desenvolvimento de um projeto mais amplo cujo objetivo é determinar regras de operação ótima para o sistema integrado dos reservatórios *Jucazinho* e *Carpina* visando um melhor aproveitamento dos recursos hídricos da região compreendida pelos mesmos.

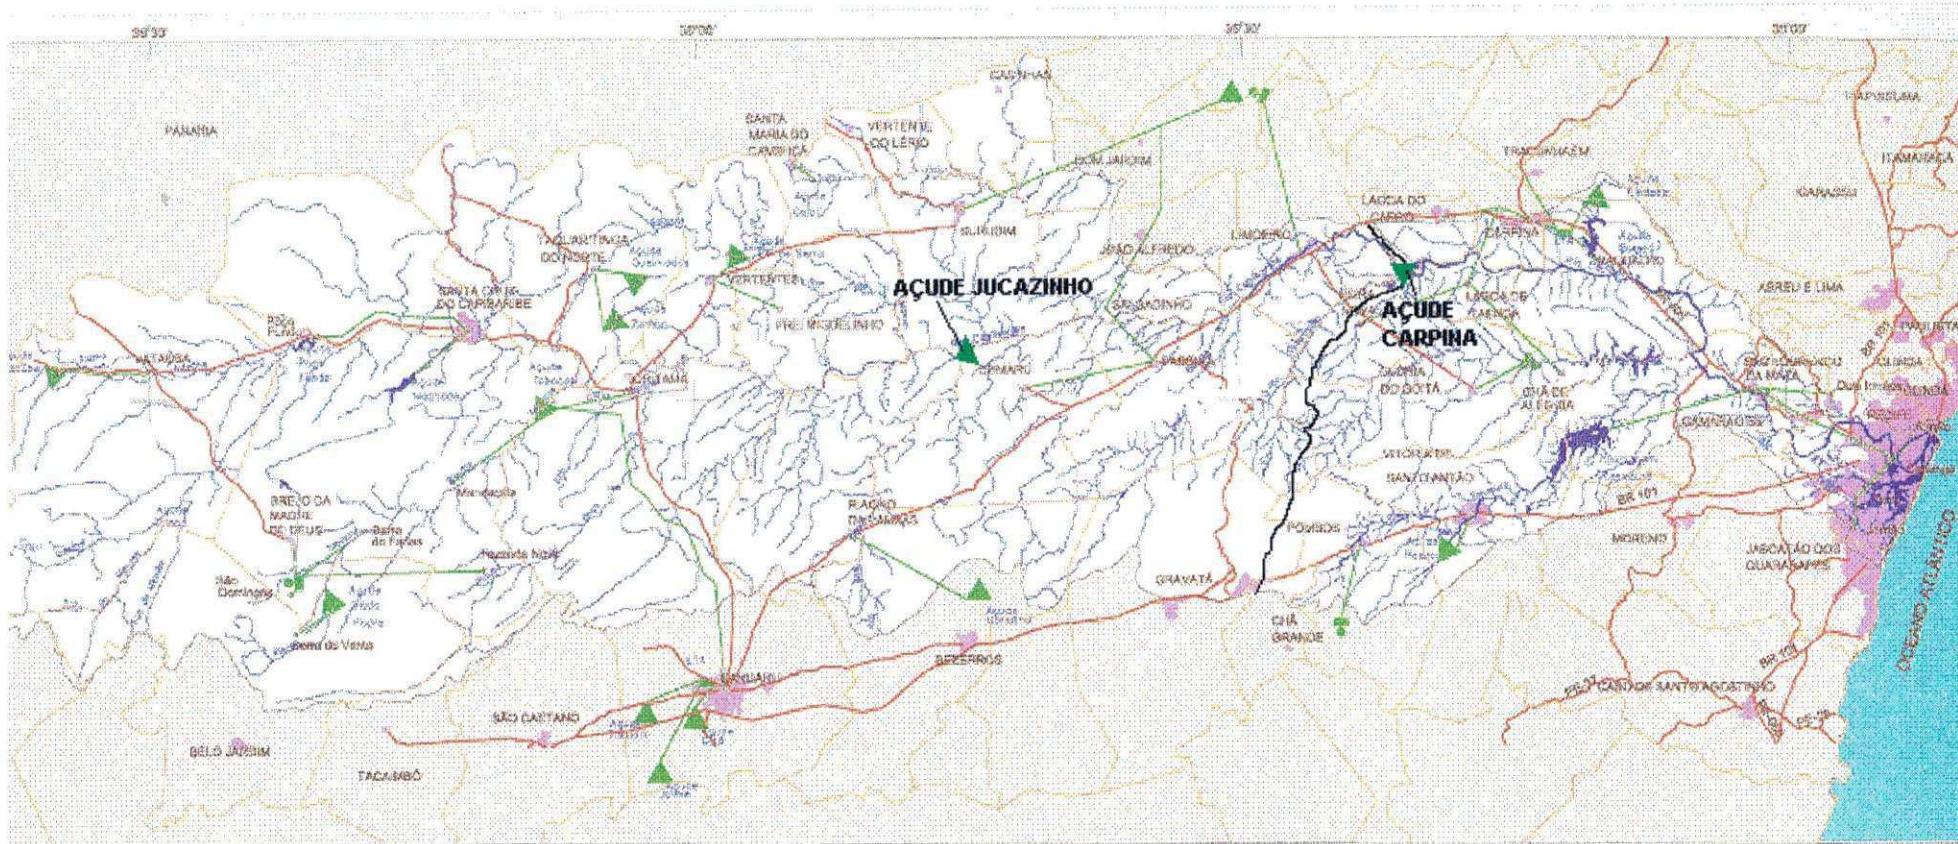

A principal ajuda deste trabalho de estágio foi no desenvolvimento de programas de computador que permitiram a análise mais rápida e precisa dos dados hidrológicos pertinentes a região. Além dos resultados apresentados neste relatório ainda estão sendo desenvolvidos atualmente outros programas para ajuste das curvas cota-área-volume e para modelagem de modelos de chuva-deflúvio.
